The E_2 -term of the Adams-Novikov spectral sequence converging to the p -local stable homotopy groups of spheres is

$$E_2^{s,t} = \text{Ext}_{BP_*(BP)}^{s,t}(BP_*, BP_*),$$

so this object is of great interest.

The chromatic resolution

The telescope conjecture

Recall that $BP_* \cong \mathbf{Z}_{(p)}[v_1, v_2, \dots]$, where $|v_n| = 2(p^n - 1)$, and

$$\Gamma := BP_*(BP) \cong BP_*[t_1, t_2, \dots], \text{ with } |t_i| = 2(p^i - 1)$$

which has a Hopf algebroid structure.

The E_2 -term of the Adams-Novikov spectral sequence converging to the p -local stable homotopy groups of spheres is

$$E_2^{s,t} = \text{Ext}_{BP_*(BP)}^{s,t}(BP_*, BP_*),$$

so this object is of great interest. It can be studied with the long exact sequence of $BP_*(BP)$ -comodules

$$0 \rightarrow BP_* \rightarrow M^0 \rightarrow M^1 \rightarrow M^2 \rightarrow M^3 \rightarrow \dots,$$

the **chromatic resolution**.

The chromatic resolution (continued)

$$0 \rightarrow BP_* \rightarrow M^0 \rightarrow M^1 \rightarrow M^2 \rightarrow M^3 \rightarrow \dots$$

This question occupied me for several years.

Doug Ravenel

LOCALIZATION WITH RESPECT TO CERTAIN PERIODIC HOMOLOGY THEORIES

By DOUGLAS C. RAVENEL*

This paper represents an attempt, only partially successful, to get at what appear to be some deep and hitherto unexamined properties of the stable homotopy category. This work was motivated by the discovery of the pervasive manifestation of various types of periodicity in the E_2 -term of the Adams-Novikov spectral sequence converging to the stable homotopy groups of spheres. In section 3 of [34] and section 8 of [41], we introduced the chromatic spectral sequence, which converges to the above E_2 -term. Unlike most spectral sequences, its input is in some sense more interesting than its output, as the former displays many appealing patterns which are somewhat hidden in the latter (see section 8 of [41] for a more detailed discussion). It is not so much a computational aid (although it has been used [34] for computing the Novikov 2-line) as a conceptual tool for understanding certain qualitative aspects of the Novikov E_2 -term.

Since the Novikov E_2 -term is a reasonably good approximation to sta-

The telescope conjecture

Suppose we have a generalized homology theory represented by a spectrum E . We say a spectrum Z is E -local if, whenever $f : A \rightarrow B$ is an E_* -equivalence, that is a map inducing an isomorphism $E_*A \rightarrow E_*B$, then the induced map

$$f^* : [B, Z] \rightarrow [A, Z]$$

is also an isomorphism.

Bousfield localization (continued)

Doug Ravenel

Theorem (Bousfield localization of spectra 1979)

For a given E there is a coaugmented functor L_E such that for any spectrum X , $L_E X$ is E -local and the map $X \rightarrow L_E X$ is an E_ -equivalence.*

Bousfield equivalence (continued)

$$\langle E \rangle \vee \langle F \rangle := \langle E \vee F \rangle \quad \text{and} \quad \langle E \rangle \wedge \langle F \rangle := \langle E \wedge F \rangle.$$

These two operations satisfy the expected distributive law. A collection with such operations is called a **lattice**, and this particular collection is called the Bousfield **lattice A**.

For any spectrum E , $\langle E \rangle \vee \langle E \rangle = \langle E \rangle$, but there are spectra E for which $\langle E \rangle \wedge \langle E \rangle \neq \langle E \rangle$.

The collection of classes $\langle E \rangle$ for which $\langle E \rangle \wedge \langle E \rangle = \langle E \rangle$ is called the **Bousfield distributive lattice DL**. It includes the classes of all connective spectra and all ring spectra.

The **complement** (if it exists) $\langle E \rangle^c$ of $\langle E \rangle$ is a class with

$$\langle E \rangle^c \vee \langle E \rangle = \langle S \rangle \quad \text{and} \quad \langle E \rangle^c \wedge \langle E \rangle = \langle * \rangle.$$

The collection of classes with complements forms a **Boolean algebra BA**.

Recall that L_∞ denotes localization with respect to the Bousfield class

$$\bigvee_{n \geq 0} \langle K(n) \rangle.$$

A p -local spectrum is **harmonic** if $X \simeq L_\infty X$. It is **dissonant** if $L_\infty X \simeq *$, meaning that $K(n)_* X = 0$ for all n . It follows from the definitions that **there are no essential maps from a dissonant spectrum to a harmonic one.**

Some conjectures

I ended the 1984 paper with a list of conjectures, all but one of which (the [telescope conjecture](#)) were proved within a 15 years, most by Hopkins and various collaborators. I have already mentioned some of them. I will state some more of them here as theorems.

Nilpotence Theorem (Devinatz-Hopkins-Smith 1988)

- 1 For a finite spectrum X , a map $v : \Sigma^d X \rightarrow X$ is nilpotent iff $MU_*(v)$ is nilpotent.
- 2 For a finite spectrum X , a map $g : X \rightarrow Y$ is smash nilpotent if the map $MU \wedge g$ is null homotopic.
- 3 Let R be a connective ring spectrum of finite type, and let $h : \pi_* R \rightarrow MU_* R$ be the Hurewicz map. Then $\alpha \in \pi_* R$ is nilpotent when $h(\alpha) = 0$.
