I andweber-Stong LRS 1993

"Determination of $H^*(BO(k, \dots, \infty), Z_2)$ and $H^*(BU(k, \dots, \infty), Z_2)$ " appeared in the AMS Transactions in 1963.

It was a tour de force computation with the Serre spectral sequence and the Steenrod algebra.

It was the first determination of the cohomology of an infinite delooping of an infinite loop space, other than the Eilenberg-Mac Lane spectrum.

It appeared while Bob was in the Army.

Mod 2 cohomology of the connective covers of BO and BU, 1963, continued

The main result of the paper implies that

$$H^*(bo; \mathbf{Z}/2) = A \otimes_{\mathcal{A}(1)} \mathbf{Z}/2$$

where A(1) denotes the subalgebra of the mod 2 Steenrod algebra A generated by Sq^1 and Sq^2 ,

and

 $H^*(bu; \mathbb{Z}/2) = A \otimes_{Q(1)} \mathbb{Z}/2$

where Q(1) denotes the subalgebra generated by Sq^1 and $[Sq^1, Sq^2]$.

These results are indispensable for future work on Spin cobordism and connective real and complex K-theory.

The question that Stong addressed is What is the image of $\eta : \pi_*(MU) \to H_*(MU)$? Two facts were already known about this:

- (i) Tensoring both side with the rationals converts η into an isomorphism, so the image of η has locally finite index.
- (ii) The Atiyah-Hirzebruch Riemann-Roch theorem (which was proved using K-theory) says that certain integrality relations must hold among these numbers.

If $\delta=\varepsilon=1,$ then φ is the signature.

If $\varepsilon = 0$ and $\delta = -\frac{1}{8}$, then φ is the \hat{A} -genus.

We now know that Λ need only be an algebra over the ring $\mathbf{Z}[1/2][\delta,\varepsilon]$, which can be interpreted as a ring of modular forms.

The manifolds on which φ vanishes admit semi-free S^1 -actions (since $\mathbb{C}P^{2n-1}$ does), and $\varphi(M)$ is an obstruction to the existence of such an action.

In the past 20 years there has been a lot of interest in interpreting such a genus geometrically or analytically.

Theory

Periodic cohomology theories defined by elliptic curves appeared in the proceedings of the Čech centennial conference of 1993.

In it we considered the genus defined above by Ochanine with values in $\mathbb{Z}[1/2][\delta, \varepsilon]$, regarded as a homomorphism out of the complex cobordism ring MU_* .

Whenever one has an R-valued genus φ on MU_* , one can ask if the functor

 $X\mapsto MU^*(X)\otimes_{arphi} R$

is a cohomology theory, i.e., whether it has appropriate exactness properties.

The Landweber Exact Functor Theorem of 1976 gives explicit criteria for such exactness.

The Ochanine genus $\varphi: MU_* \to \mathbf{Z}[1/2][\delta, \varepsilon]$ does not satisfy these criteria.

We showed that it becomes Landweber exact after inverting either ε or $\delta^2 - \varepsilon$.

This means that if R is the ring obtained from $\mathbb{Z}[1/2][\delta, \varepsilon]$ by inverting one or both of these elements, then the functor

 $X \mapsto MU^*(X) \otimes_{\varphi} R$

is a cohomology theory and therefore representable by the elliptic cohomology spectrum $E\ell\ell$.

 $C[\delta, \varepsilon]$ is naturally isomorphic to the ring $M_*(\Gamma_0(2))$ of modular forms for the group $\Gamma_0(2) \subset SL_2(\mathbf{Z})$, with δ and ε having weights 2 and 4, respectively.

This isomorphism sends the subring $M_* = \mathbb{Z}[\frac{1}{2}][\delta, \varepsilon]$ to the modular forms whose *q*-expansions at the cusp $\tau = \infty$ have coefficients in $\mathbb{Z}[\frac{1}{2}]$.

Moreover, the localizations $M_*[\Delta^{-1}]$, $M_*[\varepsilon^{-1}]$ and $M_*[(\delta^2 - \varepsilon)^{-1}]$ correspond to the rings of modular functions which are holomorphic on \mathcal{H} (the complex upper half plane), $\mathcal{H} \cup \{0\}$ and $\mathcal{H} \cup \{\infty\}$, respectively, and whose *q*-expansions have coefficients in $\mathbb{Z}[\frac{1}{2}]$.
